

What is component?

- Reusable building blocks of UI in React
- Each component handles its own structure logic.

1. Single Page Application (SPA)

- React App has just one HTML file
`public/index.html`
- React changes what's shown on screen without reloading page.
- It's feels fast and smooth.
- Update content dynamically with full page reloads.

2. Component-Based Architecture

- Instead of one gigante page, UI is broken into small reusable pieces called components
- Example: a Header, a Footer, a Button

3. JSX (Javascript XML)

- React lets write HTML inside Javascript
- Example: `return <h1> Hello </h1>`

Structure of React Project:

node_modules/

- Holds all dependencies (the libraries React needs)
- should not / never edit this folder manually

public/

- Static file resides here
- index.html (the only HTML file, React injects UI into it).

src/

- React code lives here
- App.js - main component (controls what you see on screen)
- index.js - entry point (loads **App** into DOM)

What is React?

A javascript library for building fast dynamic, interactive web UIs.
